The Dependence Between the Composition of the Solid and Vaporous

Phases in the Spectral Analysis of Alloys on an Iron Basis

FERIODICAL: Izvestiya Akademii nauk SSSR. Seriya fizicheskaya, 1959,

Vol 23, Nr 9, pp 1069-1072 (USSR)

ABSTRACT:

In the present paper the binary alloys Fe-Cr, Fe-Mn, Fe-Si, Fe-W, and Fe-C, as well as the ternary alloy Fe-Cr-C are investigated. The spectra were photographed by means of the ISP-22 spectrograph, and at the same time the products of evaporation were collected in a glass chamber. This glass chamber normally contained air, and only in the case of the alloy Fe-C pure oxygen was used. Investigations were carried out of arc- and spark-discharges. In both cases the time of exposure of the photos was the same. Until a sufficient quantity of products of evaporation had accumulated in the chamber for an analysis ten spectra were recorded, and after each recording the electrodes were newly sharpened. The experiments in the arc and in the spark were repeated three times for

Card 1/3

each alloy and the accumulated products of evaporation were

APPROVED FOR RELEASE: 08/10/2001 CIA-RDP86-00513R000619220014-6" The Dependence Between the Composition of the Solid and Vaporous Phases in the Spectral Analysis of Alloys on an Iron Basis

subjected to a thorough analysis. Figure 2 shows the results obtained according to the spark spectrum for the binary alloys. The dependence of the absolute light intensities of the alloy elements on the quantity of substance in the solid and in the vaporous phase is shown. In both cases this dependence is linear, and it was found that the substance quantity in the arc is greater by approximately one order of magnitude than in the spark. Further, the entry velocity of the substances into the gas cloud is investigated depending upon concentration in the solid phase. The products condensing in the glass chamber were analyzed on this occasion. The entry mechanism of the elements entering the spark was found to be qualitatively equal for the systems Fe-Mn, Fe-W, Fe-Cr, Fe-Cr-C and Fe-Si. The entry velocity of iron has a maximum. It follows from the experiments that for the systems Fe-Cr, Fe-Cr-C, Fe-Mn and Fe-Si the concentration of atoms in the vaporous and in the solid phase are equal in the spark, and that for the system Fe-Cr this is the case also in the arc. The deviation of the linear dependence of the system Fe-Mn with 12% Mn in the arc is briefly discussed, and it is found

Card 2/3

The Dependence Between the Composition of the Solid and Vaporous Phases in the Spectral Analysis of Alloys on an Iron Basis

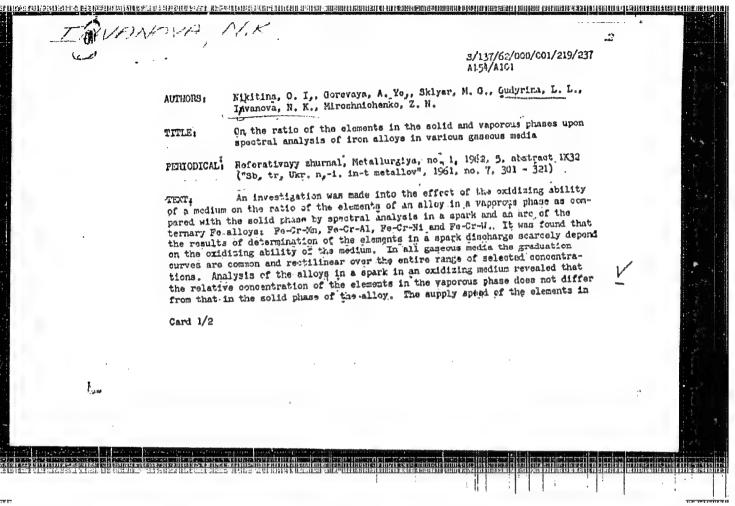

that for most alloys the relative concentrations of atoms in the solid and in the gaseous phases are squal, whereas the entry velocities of the sample depend on its chemical composition. The dependence of thermal conductivity and of the electric resistance on the composition of the alloy in these alloys shows a maximum of the former and a minimum of the latter, and agrees with a maximum of the substance escape from the solid alloy. The authors thank V. K. Prokof'yev for his interest in this work and for his advice. There are 3 figures.

TITLE:

Effect of supplementary-electrods material on the composition of the vapor phase in the spectral analysis

of ferrous metals

PERIODICAL:

Ukrayins'kyy fizychnyy zhurnal, v. 7, no. 5, 1962,

523 - 528

TEXT: The composition of iron alloys in the vapor phase and the intensity of the analytic lines were studied as a function of the material of the supplementary electrode. The investigation had 2 objects: a) Determination of the composition of the vapor phase by the colorimetric method of analysis of condensates. b) Determination of line intensity by the method of linear absorption. The ternary alloys Fe-Cr-Ni and Fe-Cr-W were investigated, as well as commercial alloys. The supplementary electrode was made of rods of the same material as the investigated alloy, or of copper, carbon and aluminum. It was established that the material of the supplementary electrode Card 1/3

Effect of supplementary-electrode ...

PART HE LEAST THE PROPERTY OF THE PARTY OF T

affects the rate of entry of the elements into the vapor phase and the discharge temperature, thereby affecting the absolute intensity of the spectral lines. The rate of entry increases if the supplementary electrodes are replaced in the following order: Carbon, copper, self-electrode. The curves Cr-line intensity versus concentration undergo a parallel shift on replacing the electrodes, whereas the corresponding curves for Ni and W are shifted at an angle. The rate of entry of the elements is related to the physical and chemical properties of the alloy and of the electrode. The temperature of the discharge cloud changes as follows (depending on the type of supplementary electrode): Tcarbon > Tself > Tcopper > Talum. The intensity of the spectral lines of Ni changes in a greater measure than that of Cr, if the electrodes are replaced. The ratio of the concentration of the alloying element to that of iron in the vapor phase, remains practically unchanged (as compared to the solid phase) if carbon and self-electrodes are used, and varies somewhat if coppor electrodes are used. The graduation curves undergo a parallel shift if this ratio changes. In conclusion, In order to determine the concentration of elements in the investigated alloys, spark analysis Card 2/3

TITLE: The influence of nickel-interlayer thickness on the structure and properties of clad steel

SOURCE: Metallovedeniya i termicheskaya obrabotka metallov, no. 11, 1966,

TOPIC TAGS: metal joining, bimetal, nickel plating, metal cladding, steel /Kh18N10T steel, Kh17N13M2T steel

ABSTRACT: The thickness of a nickel interlayer plays a major role in promoting or inhibiting diffusion processes at the boundaries of metal joints and affects the properties and structure of the boundary zone. To determine this effect with respect to the strength of the joint and the structure of the bimetal, investigations were carried out on specimens made from laboratory and industrial clad steel.

ACC NR: AP7000597

The laboratory test pieces were made of rolled packs of Kh18N10T and St. 3sp types of steel with and without nickel interlayer, the thickness of the interlayer being 10, 25, 40, 65, and 90 microns. The tests were conducted for shear and tensile strength, notch toughness, cohesion strength, metallographic investigations, and spectrum analysis. The industrial test pieces were made of 10-14-mm-thick clad-steel sheets with a cladding layer of Kh17N13M2T steel, and basic layer from 20K type steel " Ithout ant with nickel plate of a thickness of 25-30, 40, 50, 65, and 90 microns. The cohesion strength of both layers is found to increase as the thickness of the nickel interlayer is increased. The latter also affects diffusion at the metal layer interface and as a result the hardness and microhardness, as well as changes in the concentration of alloying elements. The maximum carbon consentration is found to be inversely proportional to the thickness of the nickel interlayer. The same is observed with respect to carbon diffusion. In steel clad without interlayer, there occurs complete decarbonization of the boundary layer of the noncarbon steel. A nickel interlayer lowers decarbonization of the boundary layer of St. 3sp steel and hinders the enrichment of the cladding steel in carbon. [KP]

TITLE: Spectral methods of determining rare elements in steel SOURCE: Ref zh. Khim, Part I, Abs. 3G117 REF SOURCE: Sb. tr. Ukr. n.-i. in-t metallov, vyp. 11, 1965, 393-404 TOPIC TAGS: njobium, zirconium, spectrographic analysis, hafnium, tantalum, cerium ABSTRACT: 116 (0.03-1%) is determined by spark excitation with a carbon electrode in the lines No 3094.1-Fe 3083.7 A. The standards are steel specimens in which the No content was established by means of auxiliary powdered synthetic standards obtained by dissolving steel and measuring out an No solution. The spectra of 2r and Hf for concentrations of 0.03-0.5% are excited in a condensed spark. The upper electrode for 2r is an iron electrode, and for Hf, a copper electrode. The analytical lines were: Zr 3391.9-Fe 3323.0, and Hf 2638.7-Fe 2635.8 A. The standards are prepared in the same manner as for No. Tantalum in concentrations of 0.03-0.3% is determined with arc excitation in the lines Ta 2653.2-Fe 2647.5. The standards are steel specimens which have undergone chemical analysis. The spectrum of cerium is excited in an arc discharge of alternating current with an upper Al electrode. The lines Ce 3201.7-Fe 3202.5 A are measured. The standards are specimens which had undergone chemical analysis. ISP-22 and ISP-28 spectrographs are employed. The mean error of the analysis is 10%. "Spectrophotometric Study of Bright B-Stars in the Pleiades and in Orion" Izv. AN Arm SSR, Ser. Fiz.-Matem., Yestectv. i Tekhn. n., 6, No.5-6,1953, pp 87-98

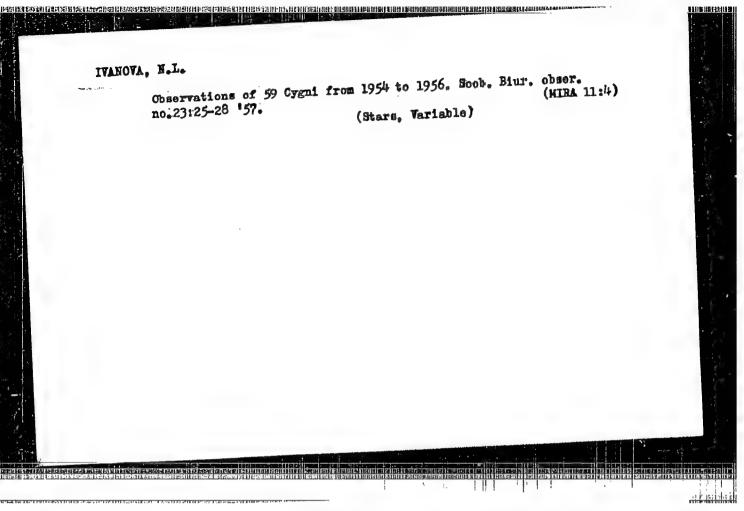

A total of 2h spectrograms of 12 stars in the region of lambda 5600-3000 were obtained by means of the ASI-5 telescope. Spectrophotometric temperatures were determined for the spectral regions on both sides of Balmer limits, as well as the jump magnitude D near this limit. Alpha Lyrae was taken as standard star. The D values are in good agreement with those by Chalonge and Barbier. (RZhAstr, No 11, 1954)

Much of the work on colorimetric observations of clusters, cometary nuclei and galaxies is being done with the 21" Schmidt telescope acquired in 1954; it has a mirror and correction lens of identical diameter, also supplied with an objective prism, making possible obtaining the spectra of several hundred stars simultaneously. Several years ago the observatory acquired a 40" Schmidt telescope with a spherical mirror 131 cm in diameter and a meter correction lens for correcting aberrations of the mirror. This telescope has three objective prisms with different disporsions. This instrument can be used for obtaining photographs of stars approximately to the 21st magnitude and simultaneously obtaining the spectra of several thousand stars to the 16th magnitude and even fainter. This is used primarily for observing galaxies. At present the Leningrad plant is constructing a modern reflector with a 2.6-m mirror which will be used for study of both distant and near galaxies. The observatory has interference radio telescopes which operate at 0.5, 1.5 and 4.2 m. There is a large interference radio telescope with an area of 5,000 square meters. Three photographs show Byurakan instruments and buildings. Much of the article is a well-presented commentary on the work program of Byurakan astronomers. Orig. art. has: 6 figures. sov/1319

Sulfur-organic compounds were separated from kerosene fractions of petroleum and physical constants (including molecular formulas, refractive indices, etc.) were determined corresponding to momo-, bi- and tricyclic sulfides. Experimental data on the fractional distillation of these compounds (which vaporized at 209-210°C) compared with known data identified them as 3-butylthicphanes [tetrahydro 3-butylthicphenes]. A.D. Biktasheva and N.S. Lyubopytova carried out the spectrographic analyses.

ABSTRACT: The crystallization of three different types of lithium glass starting with the binary system Li₂O-SiO and gradually adding photosensitive additives (Ag+CeO₂, K₂O, Al₂O₃) was investigated by the thin layer method in ultraviolet light. Investigation of the crystallization process on small glass fragments made it possible to study the formation of microcavities produced by gas bubbles, larger cavities and intermediate dendritic structures. The

presence of expansion microzones was demonstrated in which the material breaks to form microcavities. In the expansion zones, the nature of the crystallization shifts slightly toward the formation of solid solutions with increased SiO₂ content of the liberation of free SiO₂. By introducing photosensitive additives (Ag+CeO₂) into glass, the finest distribution of the gas cavities or expansion microzones can be assured throughout the glass. This effect was obtained during crystallization in an irradiated glass with 20% Li₂O, but in another glass the effect was obtained only after crystallization with preliminary irradiation. The fine distribution of gas cavities in the crystalline substance is the reason for brown colors of different intensities in the fragments. This gives the impression of a 'black' substance and its mobility during the displacement of the expansion zones. The crystallization of SiO₂ in the form of cristobalite, tridymite or quartz proceeds inside the gas cavities, and preliminary irradiation causes the crystallization equilibrium to shift toward a higher quartz content. AUTHOR: [vanova, N. M.: Kuklina, G. H.; Sedunov, Yu. S.

TITLE: Method for measuring the ionic spectrum from a high meteorological tower

SOURCE: Issledovaniye nizhnego 300-metrovogo sloya atmosfery*. Hoscow, 1963.

92-101

TOPIC TAGS: meteorology, meteorological tower, electrical field, ionic spectrum, atmospheric electricity

ABSTRACT: High meteorological towers are very valuable for continuous monitoring of a variety of parameters (wind velocity and pulsation, temperature, pressure, etc.) which affect the measurable characteristics of atmospheric electricity, since observations can be made in all kinds of weather at altitudes up to 310 meters. However, the problem arises of distortions in the readings due to the tower itself. The authors therefore calculated the distribution of the electrical field and ionic density around a tower and used these calculated deflections to devise a method for measuring the concentration and spectrum of light ions around a tower. The results show that the field voltage is increased and the direction changed near a tower, the horizontal component of the field increasing with height and the vertical component increasing with distance from the tower. The ionic spectrum is also

ACCESSION NR: AT4010230

changed near a tower, although at a distance, the concentrations of positive and negative ions become equal. In clear weather, there is a "dead" zone for negative ions around a tower, the radius of which increases with field voltage, height, and ionic mobility and decreases with increasing wind velocity. Orig. art. has: 7 figures and 16 formulas.

Abstract

: The dynamics of the distribution of tubercular bacteria (TB) and the morphological changes on the site of infection and internal organs were studied in 118 mice. TB of a bovine type were injected under the skin of the inguinal region in a dose of 0.5 mg. 113 animals were destroyed in

> groups of 14-15 in periods from 24 hours to 160 days; 5 perished from tuberculosis in periods from the 290th to the 348th day of infection. It was demonstrated that in mice a generalized tubercular process is developed at the subcutaneous injection. From the very first days, infections from the organs and tissues are filled with TB. From the subcutaneous nidus of the site of infection and from regional lymphatic ganglia, TB was transmitted to the internal organs. The authors consider that white mice, infected subcutaneously, may serve as models for unrefined experiments. --M. Ya. Boyarskaya

TITLE:

Automatic Phase Control With Nonlinear Filter

PERIODICAL: Radiotekhnika i elektronika, 1960, Vol.5, No.11,

pp.1774-1785

In automatic phase control of oscillator frequency, the degree of noise filtering must decrease as the lock-in range The article considers a nonlinear integrating network at the output of the phase detector consisting of opposed biased diodes in parallel with the integrating resistance (Fig.4). small frequency deviation, hence with low output voltage from the phase detector, the circuit has a high time constant and good filtering properties. At large frequency (phase) excursion, the diodes short-circuit the resistance and the lock-in range approaches its maximum value. The equations of the system are derived assuming that the entire system except the filter is inertialess, the reactance tube characteristic is an unlimited straight line and that frequency modulation is not accompanied by parasitic amplitude modulation. The behaviour of the system is Card 1/2

Abstract: The content of total and metabolized Zn in the various soils of the republic varies respectively between 21.6 and 43.7 mg. and between 0.5 and 26.0 mg. per kilogram of soil. The greatest quantity of free zinc is concentrated in the upper humas horizons. In turf-peat-podzol and podzol soils the A2 horizon contains the smallest quantity of Zn. The results of mapping the soils according to the mobile Zn content of the humas horizon are discussed briefly. The following five groups of soils are portrayed schematically: I -- turf-peat-carbonate: up to 1.0 mg.
